

Probing QGP properties with strangeness

Jan Rafelski

Department of Physics, The University of Arizona, Tucson, AZ 85721
Seminar at Wroclaw, June 29, 2018

Beginning with the CERN SPS experiments 30 years ago we search for the understanding of how energy becomes matter, that is we study the hadronization of primordial phase of matter, quark-gluon plasma. Today the ALICE is the experiment at the CERN LHC build predominantly to study this process. The key information is derived in study of multistrange hadrons which carry information both, about the process of matter production (hadronization) $E \Rightarrow mc^2$, as well as about earlier stages when entropy and strangeness are produced. Very recent results show that even a relatively small pp and pA collisions at the LHC energy-scale are creating the new quark-gluon plasma (QGP) phase of matter.

What is special with RHI collisions & Quark Gluon Plasma?

- ① **RECREATE THE EARLY UNIVERSE IN LABORATORY**
Recreate and understand the high energy density conditions prevailing in the Universe when matter formed from elementary degrees of freedom (quarks, gluons) at about $20 \mu\text{s}$ after the Big-Bang.
- ② **PROBING OVER A 'LARGE' DISTANCE THE (DE)CONFINING QUANTUM VACUUM STRUCTURE**
The quantum vacuum, the present day relativistic æther, determines prevailing form of matter and laws of nature.
- ③ **STUDY OF THE ORIGIN OF MATTER & OF MASS**
Matter and antimatter created when QGP 'hadronizes'. Mass of matter originates in the confining vacuum structure
- ④ **PROBE ORIGIN OF FLAVOR**
Normal matter made of first flavor family ($d, u, e, [\nu_e]$). Strangeness-rich quark-gluon plasma the sole laboratory environment filled 'to the rim' with 2nd family matter ($s, c, [\mu, \nu_\mu]$). and considerable abundance of b and even t .
- ⑤ **PROBE STRONGEST FORCES IN THE UNIVERSE**
For a short time the relativistic approach and separation of large charges $Ze \leftrightarrow Ze$ generates EM fields 1000's time stronger than those in Magnetars; strongfields=strong force=strong acceleration

Phases of hadronic matter have roots in this room

ABSTRACT

THERMODYNAMICS OF NUCLEAR MATTER FROM THE
STATISTICAL BOOTSTRAP MODEL

R. Hagedorn, I. Montvay and J. Rafelski

CERN -- Geneva

Lecture given at the
Workshop on Theoretical Physics
"Hadronic Matter at Extreme Energy Density",
Erice -- October 13-21, 1978

Ref.TH.2605
16 December 1978

We study the properties of nuclear matter within the framework of a modified and generalized statistical bootstrap model in which the volume of a fireball grows with its mass. We find that the such described nuclear matter can exist in two phases. In particular we consider in a numerical example the high temperature ($T \leq T_0 \approx 150$ MeV) regime of the gaseous phase with a density of less than ~ 0.75 of normal nuclear density.

Phase Transitions in the Statistical Bootstrap Model with an Internal Symmetry

Abstract. The connection between the statistical bootstrap model with an arbitrary symmetry group and the thermodynamical description of hadronic matter is considered. A relationship is given between an internal symmetry and the appearance of a multiphase structure.

Acknowledgement. One of the authors (L.T.) is very indebted to Professor R. Hagedorn for discussions and helpful comments.

Received 11 August 1980

We discuss central collisions between heavy nuclei of equal baryon number at extremely high energies. We make a crude estimation of the energy deposited in the fragmentation regions of the nuclei. We argue that the fragmentation-region fragments thermalize, and two hot fireballs are formed. These fireballs would have rapidities close to the rapidities of the original nuclei. We discuss the possible formation of hot, dense quark plasmas in the fireballs.

collisions of very-high-energy nuclei are to be the subject of intense experimental investigation in the next few years.

shall discuss the theory of such collisions in paper. We shall concentrate on describing al collisions between nuclei of equal baryon

The fragmentation regions of the nuclei represent an area of phase space where new phenomena might occur. "Fragmentation region" refers to the region of phase space of particles where the particles have longitudinal momentum close to that of the original nucleus projectile or target. In the fragmentation region, the nucleus fragments and inelastically produced particles might form a hot, dense fireball. We shall soon see that this forma-

At CERN: Strangeness a popular QGP signature

I argued 1980-81 that anti-strangeness in QGP can be more abundant than anti-light quarks. Many experiments followed.

A: There are many strange particles allowing to study different physics questions ($q = u, d$):

$$K(q\bar{s}), \quad \bar{K}(\bar{q}s), \quad K^*(890), \quad \Lambda(qqs), \quad \bar{\Lambda}(\bar{q}\bar{q}\bar{s}), \quad \Lambda(1520) \\ \phi(s\bar{s}), \quad \Xi(qss), \quad \bar{\Xi}(\bar{q}\bar{s}\bar{s}), \quad \Omega(sss), \quad \bar{\Omega}(\bar{s}\bar{s}\bar{s})$$

B: Production rates hence statistical significance is high.

C: Strange hadrons are subject to a self analyzing decay

...till today we live with some consequences

Fulbright Flex researcher Johann Rafelski at Wigner Centre for Physics

Johann Rafelski from *The University of Arizona* in Tucson, USA, was awarded a Senior Flex Fulbright Fellowship to visit in Summer 2019 and 2020 the Wigner Research Centre for Physics in Budapest. Eugene Paul Wigner was a Hungarian-American theoretical physicist, engineer and mathematician who won Noble prize in 1963. The Wigner Institute is the largest Hungarian fundamental science research center where the research legacy of Prof. Wigner continues. Rafelski will be given the title "Distinguished Wigner Professor" by this institute.

Rafelski's primary host is Prof. Tamás Biró, vice-director of the Institute for Particle and Nuclear Physics, incorporating half of the Wigner Centre. Prof. Rafelski is well known to the Hungarian Physics community, and this relation has roots that go back nearly 40 years, when the young Dr. Rafelski proposed "Strangeness Signature" of the primordial phase of matter, the quark-gluon plasma. At that time a bit younger graduate student Tamas Biro was charged by his supervisor Prof. Dr. Joseph Zimanyi to review Rafelski's ideas and to improve the mathematical-theoretical description. The effort of Biro and Zimanyi helped Rafelski to refine his proposal further which became one of the corner stones of the research field where, since then, a few thousand scientists perform experiments at largest particle colliders simulating the Big-Bang conditions in the laboratory.

A low level connection of Rafelski with Budapest continued for the following decades. For example after Rafelski started the new conference series "Strangeness in Quark Matter", within a few years in late '90s the meeting took place in Budapest. However, a direct collaborative research effort of Rafelski and Biro did not occur even though both work in parallel to this day in several research fields. This possibility has been opened now by the Fulbright Flex Program.

(C) Hungarian-American Fulbright Commission

Both researchers seen in the picture came to visit the Fulbright office in Budapest during a preparatory visit June 19, 2018 (Rafelski on right). They are looking forward to a fruitful and rewarding joint effort addressing the most intriguing current questions in the area of fundamental theoretical physics.

Instant success of strangeness signature proposal

First strangeness signature 1980: CPOD, WROCLAW, June 2, 2016

ratio of \bar{s}/\bar{q} in $\bar{\Lambda}/\bar{p}$ triggers Marek's strange interest!

What we intend to show is that there are many more \bar{s} quarks than antiquarks of each light flavour. Indeed:

$$\frac{\bar{s}}{\bar{q}} = \frac{1}{2} \left(\frac{m_s}{T} \right)^2 K_2 \left(\frac{m_s}{T} \right) e^{M/3T} \quad (23)$$

The function $x^2 K_2(x)$ is, for example, tabulated in Ref. 15). For $x = m_s/T$ between 1.5 and 2, it varies between 1.3 and 1. Thus, we almost always have more \bar{s} than \bar{q} quarks and, in many cases of interest, $\bar{s}/\bar{q} \sim 5$. As $\mu \rightarrow 0$ there are about as many \bar{u} and \bar{q} quarks as there are \bar{s} quarks.

A Study of Λ -Production
in Central Nucleus-Nucleus Interactions
at a Momentum of 4.5 GeV/c Per Incident Nucleon

Transverse momenta and rapidities of Λ 's produced in nucleus-nucleus collisions at 4.5 GeV/c per nucleon /CC, CZr, CPb, OPb/ have been studied and compared with Re-Li interactions at the same incident momentum. Polar hyperons was found to be consistent within the errors ($\langle p_T \rangle = 0.06 \pm 0.11$) for 274 Λ 's from central collisions of A/A. production ratio was estimated to be less than confidence level.

The analyzed experimental data were obtained using 2 m streamer spectrometer SKM-200.

The investigation has been performed at the Laboratoire d'Énergies, JINR.

New State of Matter created at CERN

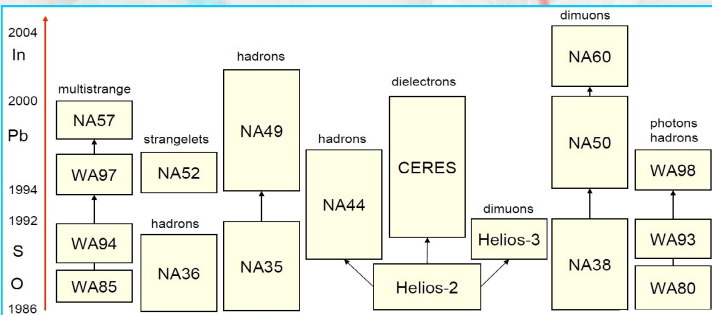

10 Feb 2000

At the April 2005 meeting of the American Physical Society, held in Tampa, Florida a press conference took place on Monday, April 18, 9:00 local time. The public announcement of this event was made April 4, 2005:

EVIDENCE FOR A NEW TYPE OF NUCLEAR MATTER At the Relativistic Heavy Ion Collider (RHIC) at Brookhaven National Lab (BNL), two beams of gold atoms are smashed together, the goal being to recreate the conditions thought to have prevailed in the universe only a few microseconds after the big bang, so that novel forms of nuclear matter can be studied. At this press conference, RHIC scientists will sum up all they have learned from several years of observing the worlds most energetic collisions of atomic nuclei. The four experimental groups operating at RHIC will present

a consolidated, surprising, exciting new interpretation of their data. Speakers will include: Dennis Kovar, Associate Director, Office of Nuclear Physics, U.S. Department of Energy's Office of Science; Sam Aronson, Associate Laboratory Director for High Energy and Nuclear Physics, Brookhaven National Laboratory. Also on hand to discuss RHIC results and implications will be: Praveen Chaudhari, Director, Brookhaven National Laboratory; representatives of the four experimental collaborations at the Relativistic Heavy Ion Collider; and several theoretical physicists.

PHASE TRANSITION IN HADRONIC MATTER WITH INTERNAL SYMMETRY *)

K. Redlich **) and L. Turko **)

CERN -- Geneva

ABSTRACT

A general formalism for the description of a thermodynamical system with internal symmetry is introduced. Results are applied to the statistical bootstrap model describing hadronic clusters with isospin conservation taken into account and equations of state are obtained. It is shown that at the sufficiently high energy density, a phase transition occurs. A new phase is an intermediate one between hadronic matter and a quark-gluon plasma phase.

Abstract

Experimental results on strange anti-baryon production in nuclear S–W collisions at 200 A GeV are described in terms of a simple model of an explosively disintegrating quark-lepton plasma (QGP). The importance of the strange anti-baryon signal for the identification of the QGP state and for the diagnosis of its properties is demonstrated.

Chemical nonequilibrium and deconfinement in 200A GeV sulphur induced reactions

PHYSICAL REVIEW C

covering nuclear physics

We interpret hadronic particle abundances produced in S-Au/W/Pb 200A GeV reactions in terms of the final state hadronic phase space model and determine by a data fit of the chemical hadron freeze-out parameters. Allowing for the flavor abundance nonequilibrium a highly significant fit to experimental particle abundance data emerges, which supports the possibility of strangeness distillation. We find under different strategies stable values for freeze-out temperature $T_f = 143 \pm 3$ MeV, baryochemical potential $\mu_B = 173 \pm 6$ MeV, ratio of strangeness (γ_s) and light quark (γ_q) phase space occupancies $\gamma_s/\gamma_q = 0.60 \pm 0.02$, and $\gamma_q = 1.22 \pm 0.05$ without accounting for collective expansion (radial flow). When introducing flow effects which allow a consistent description of the transverse mass particle spectra, yielding $|v_c| = 0.49 \pm 0.01$ c, we find $\gamma_s/\gamma_q = 0.69 \pm 0.03$, $\gamma_q = 1.41 \pm 0.08$. The strange quark fugacity is fitted at $\lambda_s = 1.00 \pm 0.02$ suggesting chemical freeze-out directly from the deconfined phase.

Magic coincidence: while we battled our referee for 6 months Krzysztof Redlich enters this field with the 2 page preprint in August 1998:
Unified description of freezeout parameters in relativistic heavy ion collisions, Phys.Rev.Lett. 81 (1998) 5284-5286

Chemical reactions involving quarks

EXAMPLE: Strangeness in HG:

Relative
chemical equilibrium

Absolute
chemical equilibrium

EXCHANGE REACTION PRODUCTION REACTION

Absolute equilibrium $\gamma \rightarrow 1$ require more rarely occurring truly inelastic collisions with creation of new particles.

γ_i controls overall abundance of quark 'i' pairs	Absolute chemical equilibrium
λ_i controls difference between strange and non-strange quarks 'i'	Relative chemical equilibrium

WHY STATISTICAL HADRONIZATION MODEL... (SHM) WORKS

- a) Confinement: \Rightarrow breakup into free quarks not possible;
- b) Strong interaction: \Rightarrow equal hadron production strength irrespective of produced hadron type

\Rightarrow 'elementary' hadron yields depend only on the **available phase space**

Historical approaches:

- Fermi: Micro-canonical phase space
sharp energy and sharp number of particles
E. Fermi, Prog.Theor.Phys. 5 (1950) 570: **HOWEVER**
Experiments report event-average rapidity particle abundances,
model should describe **an average event**
- Canonical phase space: sharp number of particles
ensemble average energy $E \rightarrow T$ temperature
 T could be, but needs not to be, a kinetic process temperature
- Grand-canonical – ensemble average energy and number of particles:
 $N \rightarrow \mu \Leftrightarrow \Upsilon = e^{(\mu/T)}$

Our interest: bulk QGP fireball properties of hadron source evaluated independent of complex explosion dynamics \Rightarrow analyze integrated hadron spectra.

Decay tree (>2500 channels)

Ω^0 DECAY MODES		
Mode	Fraction (Γ/Γ_0)	Cosine level
$\Gamma_1 \quad \Lambda K^-$	$(10 \pm 3)\%$	
$\Gamma_2 \quad \Xi^0 \pi^-$	$(25 \pm 6)\%$	
$\Gamma_3 \quad \Xi^- \pi^0$	$(8 \pm 6)\%$	
$\Gamma_4 \quad \Xi^- \pi^+ \pi^-$	$(3.3^{+0.8}_{-0.7}) \times 10^{-4}$	
$\Gamma_5 \quad \Xi^0(1530)^0 \pi^-$	$< 7 \times 10^{-6}$	95%
$\Gamma_6 \quad \Xi^0 \pi^+ \pi^-$	$(5.6 \pm 2.8) \times 10^{-3}$	
$\Gamma_7 \quad \Xi^- \pi^+ \pi^-$	$< 4.6 \times 10^{-4}$	95%

$\Delta S = 2$ forbidden (ΔS) modes:

$\Gamma_8 \quad \Lambda \pi^-$	$S^2 < 2.9 \times 10^{-6}$	95%
--------------------------------	----------------------------	-----

SHM computation:

1. calculate particle yields
2. decay unstable particles
3. compare to experimental data, calculate χ^2

$$\chi^2 = \sum_{i=1}^N \frac{(f_{i,\text{theory}} - f_{i,\text{experiment}})^2}{(\Delta f_{i,\text{systematic}} + \Delta f_{i,\text{statistical}})^2}$$

Tune parameters
to minimize χ^2

Output:
Hadron yields, ratios
Physical properties

Experimental data:
integrated yield of
several hadron
species, π , K , p , Λ , ϕ

Examples SHM Analysis (Chemical Nonequilibrium)

Particle Yield Example:LHC

M. Petran, J. Letessier, V. Petracek, J. Rafelski Phys.Rev. C **88** (2013) no.3, 034907

Bulk properties from SHM yields

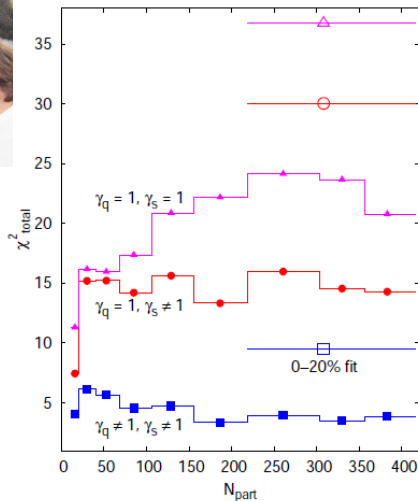

J. Letessier, J. Rafelski, Eur.Phys.J. A **35** (2008) 221-242

Chemical non-equilibrium SHM works at all centralities

Non-equilibrium

- $\chi^2/\text{ndf} \simeq 4.5/9 = 0.5$,
- constant across centrality
- improvement by factor of 3 resp. 5 comparing to $\gamma_q = 1$
- Only in peripheral collisions
 $\gamma_q \simeq 1$ maybe possible

SHARE consistent with lattice QCD

Chemical nonequilibrium + supercooling

= sudden fireball breakup

Chemical freeze-out MUST be below lattice results. For direct free-streaming hadron emission from QGP, T -SHM is the QGP source temperature, there **cannot be full chemical equilibrium**.

SPS, RHIC, LHC AA SHM Digest

- Strange antibaryon signature of QGP leads to discovery of universal properties of QGP at hadronization; differences in: Volume size, Strangeness saturation.
- Universality of fireball bulk properties across the entire reaction energy domain we express in terms of the invariant measure

- At SPS, RHIC: Baryon number deposition varies strongly as function of collision energy. This is the chemical potential dependence on collision energy. WHY? – To clarify question: why **there is no McLerran-Bjorken transparency?**

A few first analysis observations and summary

- ALICE small system results shows growth γ_s of strangeness yield with size of the system.
- Hadronization condition T a few MeV higher compared to large systems: conclusion there is less/no supercooling in less explosive expansion.
- Corresponding bulk matter properties are higher. No test of universal hadronization / conformal anomaly was as yet performed.
- Small system net flavor content universally zero (and it seems we are sensitive due to small system): there is no electric charge, etc.
- **There is no doubt that after 38 years of waiting the $pp \rightarrow AA$ ALICE results demonstrate that there are 10-20-30% canonical phase space effects: when strange pairs are few and baryon number is rare, strange antibaryons are slightly suppressed as the correct theory predicts. Dominant effect still from strangeness chemical non-equilibrium γ_s . No publication forthcoming as lack of resources prevents appropriate analysis effort.**
